

CHARACTERISTICS OF CLOSED BREEDING STATIONS OF BISON (*BISON BONASUS* L.) IN POLAND IN THE YEARS 1997-2000

Dariusz Zalewski, Wiesław A. Szczepański,
Małgorzata Wołkowska
University of Warmia and Mazury in Olsztyn

Abstract. The objective of this study was to present the general situation and conditions of lowland bison breeding in Poland in the years 1997-2000, at four Closed Bison Breeding Stations, the Wolin National Park in Międzyzdroje, the Forest Culture Center in Gołuchów, the Wildlife Park in Kadzidłowo, Municipal Enterprise for Urban Green Areas Preservation in Leszno, and eight zoological gardens.

Key words: bison, *Bison bonasus* L., closed breeding station, habitat types, enclosure capacity

INTRODUCTION

The genus *Bison* is represented by two species: the European bison (*Bison bonasus* L.) and the American bison (*Bison bison* L.). There are two subspecies within each of these species [Krasinski 1992]. Two subspecies of *Bison bonasus* L. are the lowland bison (*Bison bonasus bonasus* L.) and the highland or Caucasus bison (*Bison bonasus caucasicus*) [Krasinski 1978 following Turkin and Satunin 1904]. No pure Caucasus bison exists nowadays, as they became extinct in the wild in 1927, but there exists a lineage of free-ranging Białowieża-Caucasus bison in the Bieszczady Mountains [Jamrozy 1994].

In the 11th c. large populations of bison lived in Europe, whereas in the 19th c. they were present in the Białowieża Primeval Forest and Caucasus only [Krasinski 1978]. A Caucasus bull (named Caucasus) harvested in 1908, mated to Białowieża females, produced progeny referred to by breeders as the Białowieża-Caucasus lineage.

The lowland bison lived for the longest time under natural conditions in the Białowieża Primeval Forest. There were 727 bison in this Forest before the First World War [Bereszyński 1995]. Almost the entire herd became extinct during the War, and

Corresponding author – Adres do korespondencji: dr inż. Dariusz Zalewski, Department of Sheep, Goat and Game Management of University of Warmia and Mazury in Olsztyn, M. Oczapowskiego 5, 10-718 Olsztyn, e-mail: d.zalewski@uwm.edu.pl

the last bison was shot by a local poacher in 1919 [Bereszyński 1995, Pucek 1993]. However, this subspecies survived in small numbers in zoos. According to Bereszyński [1995], Krasiński [1978] and Olech [1998 a], a list of bison compiled in 1924 shows that only 66 animals (33♂ + 33♀) survived in the zoos around the world, including 54 (29♂ + 25♀) whose descent was well-documented. Most of them can be traced to the Caucasus bull. In 1939 the number of bison in Poland was 40 animals, and after the Second World War it increased to 44 (20♂ + 24♀), which constituted almost half of the total world population, being at that time 103 animals (43♂ + 60♀) [Olech 1998 a]. In the years 1947-1974 Poland became the main center supplying bison for reintroduction to other European states. About 200 bison were provided to 17 countries over this period [Graczyk 1981].

The objective of the present study was to present the general situation and conditions of lowland bison breeding at closed stations in Poland in the years 1997-2000.

MATERIALS AND METHODS

The experimental materials comprised lowland bison populations living in Poland [European Bison 2004]. The data presented in the paper concern the period from 1997 to March 31, 2000. They were collected at 16 closed breeding stations, whose location is shown in Figure 1. The material was gathered on the basis of questionnaires drawn up

Fig. 1. Location of closed bison breeding stations in Poland. WPN – Wolin National Park; OKL – Forest Culture Center; PDZ – Wildlife Park; MZZ – Municipal Enterprise for Urban Green Areas Preservation

Rys. 1. Położenie hodowli zamkniętych żubra w Polsce. WPN – Woliński Park Narodowy; OKL – Ośrodek Kultury Leśnej; PDZ – Park Dzikich Zwierząt; MZZ – Miejski Zakład Zieleni

for the above bison breeding stations, herds in Międzyzdroje and Gołuchów, and zoological gardens. The questions concerned the number of bison and population dynamics in particular preserves, living conditions, age structure of herds, number of calvings per year, bison exchange between stations, mortality rates and causes. Apart from the above questionnaires, the information was also collected during interviews with the employees of the Bison Breeding Stations in Białowieża, Pszczyna and Smardzewice, the Wolin National Park in Międzyzdroje and the Forest Culture Center in Gołuchów.

The numerical data concerning bison populations, number of calvings, bison exchange between stations, number of bison shot and culled, are given in a tabular form.

RESULTS AND DISCUSSION

Characteristics of closed breeding stations

Table 1 shows the number and area of enclosures for bison in zoos. The enclosure area is the largest in the zoological garden in Gdańsk-Oliwa (37.945 m^2), and the smallest – in Bydgoszcz (48 m^2) and Poznań (60 m^2). At the other centers it varies from 200 to 5.400 m^2 .

Note: habitat types as in the forest management specification.

Uwaga: typy siedlisk przyjęte w operatach urządzenia lasu.

Table 2 shows the location of the bison breeding stations, the Wolin National Park in Międzyzdroje and the Forest Culture Center in Gołuchów. The number and area of yards at closed bison breeding stations are also given, together with types of habitats and their percentages in the forest area of each station. The Bison Breeding Station in Pszczyna covers the largest area – 742.56 ha. This is an enclosed forest complex for free-ranging bison management. The Breeding Station is Białowieża also occupies an extensive area of 274.25 ha, but this includes an exhibition reserve with enclosures for other animal species as well. The smallest are the stockyards in Międzyzdroje (11 ha) and Gołuchów (19.2 ha).

Bison population dynamics in the years 1997-2000

According to Olech [1998 b], bison populations at closed breeding stations, at the current restitution stage, have reached the numbers corresponding to the capacity of a given station. However, the information collected in this study indicates that in some cases this capacity has been exceeded. For instance, at the Bison Breeding Stations in Niepołomice and Smardzewice the actual numbers of animals are much higher than their estimated capacities.

The estimates capacities of particular breeding stations, and the sex structure of bison kept there, are presented in Table 3.

The most bison (41) live at the Breeding Station in Białowieża. However, due to the fact that 10 of them are kept at the exhibition reserve, the capacity of this Station (27 to 30 bison) has not been significantly exceeded. In the year 2000 bison density at the Breeding Station in Białowieża was 6,7 ha per animal (excluding the bison kept at the reserve). Among the breeding stations analyzed, the Wolin National Park in Międzyzdroje

*Stan na 31.03. każdego roku.

and the Forest Culture Center in Gołuchów, the lowest bison density was observed at the Breeding Station in Pszczyna (28.6 ha per bison). At the other stations it varied from 1.4 ha to 3.0 ha per animal. In the year 2000 the capacity of the six preserves examined was 99 to 105 animals, whereas the total bison number was 128 (excluding those kept at the reserve in Białowieża). The total area of four breeding stations, the Wolin National Park in Międzyzdroje and the Forest Culture Center in Gołuchów was 1.171.31 ha and the total number of bison – 128, which means that the actual average area per bison was 9.2 ha, compared with the intended 11.2-11.8 ha. The environmental capacity of all closed bison breeding stations in Poland, in the years 1997-2000, was 131 to 142 animals. The lowest number of bison (153) was recorded in 1998, and the highest (176) – in 1999, which shows that every year it exceeded the capacity. The mean male to female ratio was 1 to 2, reaching the highest level, i.e. 1 to 2.4, in the year 2000 (...). The sex structure at the breeding stations examined, including the Wolin National Park in Międzyzdroje and the Forest Culture Center in Gołuchów, in the years 1997-2000, is shown in Table 4. The mean male to female ratio in successive years varied from 1:1.87

(1997) to 1:2.73 (2000). The number of females, compared with the number of males, was the highest at the Bison Breeding Station in Białowieża. In the last three years the male to female ratio was there above 1:3. Its mean value for the six stations studied was 1 to 2.29, and for all preserves (Table 4) – 1 to 2.07.

The limited capacity of the stations necessitates periodic reduction of herd size. This concerns sick and weak animals, calves born beyond the reproductive season, animals with some genetic defects. Such bison are shot (Table 5), or transported to other centers, where they can be mated with appropriately selected partners, producing progeny with the lowest possible inbreeding index. Table 5 shows that over the experimental period the highest number of bison were shot at the Breeding Station in Białowieża (18 animals). The total number of bison shot at the stations examined from 1997 to 31.03.2000 was 28, i.e. on average 7 per year, which constitutes 4.2% of the mean annual number of bison (166.75) in the period analyzed. The mean value of this parameter for the Breeding Station in Białowieża was 11.8%. It should be stressed that this level of bison elimination was lower than the expected population growth. According to Krasinski et al. [1994 a] and Krasinski and Krasinska [1994], the mean annual birthrate among free-ranging bison in the Białowieża Primeval Forest was 14.5 to 17.3% until the 1990s. In order to stabilize the Polish bison population, their number in the Białowieża Primeval Forest was regulated by approx. 10% each year, starting from the early 1970s. This allowed to maintain the bison number in the main herd at a level of 210 to 270 animals [Krasinski et al. 1994 a]. It is believed that in stable bison populations limited exploitation may be 20% a year [Krasinski et al. 1994 b].

CONCLUSIONS

The results obtained for the years 1997-2000 allow to formulate the following conclusions:

1. Over the experimental period, the numbers of bison kept at 16 closed breeding stations were as follows:

- 1997 – 165 animals (δ 58; φ 107),
- 1998 – 153 animals (δ 47; φ 106),
- 1999 – 176 animals (δ 61; φ 115),
- 2000 – 173 animals (δ 51; φ 122) (state as on March 31).

2. In Poland almost 70% of bison are kept at the Breeding Stations in Białowieża, Niepołomice, Pszczyna and Smardzewice.

3. Among the zoos examined, the zoological garden in Gdańsk-Oliwa is characterized by the largest bison enclosure area (37.945 m^2), and the Forest Park for Culture and Recreation in Bydgoszcz – by the smallest (48 m^2).

4. The Bison Breeding Station in Pszczyna covers the largest area (742.56 ha), and the bison enclosure area in the Wolin National Park in Międzyzdroje is the smallest (11 ha). At the stations examined, in the year 2000, the actual average area per bison was 9.2 ha. The total number of bison was 128.

5. The sex structure at particular closed bison breeding stations was as follows:

- 1997 r. – $1\delta : \varphi 1.84$,
- 1998 r. – $1\delta : \varphi 2.26$,
- 1999 r. – $1\delta : \varphi 1.89$,
- 2000 r. – $1\delta : \varphi 2.39$.

The mean male to female ratio over the period analyzed was 1:2.07.

6. 28 bison were shot from 1997 to March 31, 2000, as many as 18 of them at the Breeding Station in Białowieża.

7. The total number of bison shot at the stations examined over the experimental period constituted 4.2% of the mean annual number of bison (166.75).
